

**Phosphodiesterase Inhibitors,
Preparation and Therapeutic Use Thereof**

5 The invention relates to compounds and their uses, particularly in the pharmaceutical industry. The invention discloses compounds having PDE2 inhibitory activities, as well as therapeutic methods by administering said compounds, in particular for treating various diseases of the central or peripheral nervous system. It further deals with pharmaceutical compositions comprising said compounds and methods for preparing said compounds.

10

 The compounds of the present invention present a very interesting pharmacological profile, since they are inhibitors of cyclic nucleotide phosphodiesterases and in particular cGS-PDE (cGMP-Stimulated PDEs, type 2-phosphodiesterase, or PDE2).

15

 The intracellular second messenger cAMP or cGMP is broken down and deactivated by phosphodiesterase (PDE), which is classified into at least types I to XI. PDE is widely distributed in the tissue and organs of the body. Among these, type II phosphodiesterase breaks down both cAMP and cGMP and can be activated by cGMP. This type II phosphodiesterase is found in numerous tissues (adipocytes, brain, heart, 20 lungs, kidneys, blood vessels, etc.). PDE2 inhibitors are able to increase or maintain intracellular cAMP and cGMP rates and thereby find therapeutic interests in various pathologies.

 The present invention provides compounds having a high inhibiting activity on 25 PDE2, and preferably a selectivity profile with respect to other PDE isoforms, including a low action on PDE3. This selectivity profile may extend to other types of enzymes, such as adenosine deaminase. Moreover, compounds of the invention present an interesting effect on the central nervous system (anticonvulsants, anxiolytics, sedative, antidepressants) or the peripheral nervous system (against rheumatism, 30 autoinflammatory diseases, against dysfunction of liver due to ageing). They also advantageously present no perturbing effect on memory.

The compounds according to the present invention may be prepared by various methods known to those skilled in the art. Different chemical routes have been carried out and are described below.

Intermediates of general formula II, in which R₈ is OCH₃ or a OPh can be prepared using a method analogous to that reported in J. Med. Chem. 1989, Vol. 32, N°8, 1936-1942.

When R₈ is an ethoxy or an other alkoxy group, the synthesis of II could be performed starting from alkylation of 3-nitrophenol followed by reduction of the nitro group and then using the reference above.

When X is an aryl group and R₈ is a methoxy group, the synthesis of II could be performed by a Suzuki coupling between 2-bromo-5-nitroanisole and a suitable boronic acid followed by reduction of the nitro group and then using the reference cited above.

**PHARMACOLOGICAL ACTIVITY : INHIBITION OF
PHOSPHODIESTERASES**

20

Isolation of phosphodiesterases from smooth muscle

3 g of tunica media from bovine aorta was cut in small piece and homogenized in a glass potter with 7 volumes/weight of buffer A containing protease inhibitors cocktails (20 mM Tris-HCl, 0.25 M saccharose, 2mM magnesium acetate, 1mM dithiothreitol, 5 mM EGTA, 2000 U/ml aprotinine, 10 mg/l leupeptine, 10 mg/l of soybean chemotrypsin inhibitor). The homogenate was centrifuged at 875000 g for 1 h and the supernatant was then transferred in DEAE-Sephacel (15 X 1.6 cm). The column was equilibrated beforehand with a buffer B (buffer A without saccharose, d'EGTA and protease inhibitors). The column was washed until no absorption was detected at 280 nm and then eluated with linear gradient of NaCl (0-0.5 M) in the buffer B. Fractions of 3 ml volume were collected and the enzymatic activities were assessed under the conditions described

25

below in order to identify fractions containing PDE1, PDE3, PDE4 and PDE5 (Lugnier et al., Biochem. Pharmacol., 35 (1986) 1746-1751). Fractions were aliquoted and stored at -80°C until further use. PDE2 was prepared from bovine endothelial cells using the same procedure (Lugnier and Schini, Biochem. Pharmacol. 1990, 39; 75-84).

5

Protocol for the measurement of phosphodiesterase activities

Cyclic nucleotide phosphodiesterase activity was determined by radioenzymatic assay using tritiated cyclic AMP or GMP (1 μ M) as a substrate (Lugnier et al., 1986). The
10 monophosphated adenosine or guanosine released by the hydrolysis of tritiated cyclic nucleotides was transformed into tritiated adenosine or guanosine by excess of nucleotidase. The obtained nucleoside was separated from nucleotides by anion exchange chromatography. Nucleoside radioactivity was determined by liquid scintillation. All enzymatic reactions were conducted in duplicates and under conditions
15 to obtain less than 15% of substrate hydrolysis.

Measurement of PDE2 inhibition.

The concentration of substance required to inhibit 50% of the enzymatic activity (IC_{50})
20 in the presence of 1 μ M cyclic AMP was determined by non-linear regression analysis of the rate of hydrolysis (Prism, GraphPad).

Selectivity

25 The phosphodiesterase inhibitory activity of compounds was evaluated on other isoforms of phosphodiesterases such as PDE3, and PDE4 of vascular smooth muscle.

Obtained results were presented in Tables 1 and 2, showing the percentage of PDE inhibition by 10 μ M of test compound or the inhibitory concentration at which the
30 enzymatic activity is reduced by 50% (IC_{50}).

EXAMPLE C

BEHAVIOURAL TESTS

5

SWIM TEST

This test is based on the induction of alternative behaviour in rodents subjected to an acute stress. In this model, the rat or mouse placed in a container filled with water show periods of increased swimming activity and periods of relative immobility. Clinically
10 active anti-depressants have been found to delay the onset of the first phase of immobility and to reduce the total time of relative immobility.

Swiss mice were used. The animal was placed individually in the water where it remained for 6 minutes. The animal was given an accommodation period of 2 minutes.
15 During the last 4 minutes observation period, the onset of the first period of immobility and the duration of the periods of immobility were recorded.

Treatment was administered 16 minutes prior to the test. Animals were randomly distributed in 4 groups. Control group received the vehicle whereas the other 3 groups received different single dose of test compound.

20

Results are illustrated in figure 1 : Mean Duration of Phases of Immobility (s) ; N= 10; $p < 0,005$ (Dunnett's test).

Statistical analyses revealed a significant difference between groups regarding the period
25 of total immobility ($p = 0.005$). Mice treated with 0.3, 3 or 30 mg/kg of test compound showed significantly shorter time of relative immobility than control animals.

LIGHT DARK TEST

1. Purpose
30 The light dark (LD) test is used to evaluate the relative anxiety status of mice.
2. Background

The light dark paradigm in rodents is based on a conflict between the innate aversion to brightly illuminated areas and the spontaneous exploratory activity. If given a choice between a large brightly compartment versus a small dark compartment, animals spontaneously prefer the dark. Anxiolytic compounds have been found to increase the number of entries into the bright compartment and the total duration of time spent there. Anxiogenic compounds were observed to work in the opposite way.

3. Materials

Equipment

The apparatus consists of two polyvinylchloride boxes ($19 \times 19 \times 15$ cm) closed with plexiglas. One of these boxes is illuminated by a 100 W desk lamp placed 15 cm above and providing an illumination of about 4400 Lux, the other box being dark. An opaque plastic tunnel ($5 \times 7 \times 10$ cm) separates the dark box from the illuminated one.

15 Reagents

- Test substance
- Vehicle

4. Methods

20 Step 1 - drug treatments:

Animals are randomly assigned to test compounds of the invention (test substances) and control groups. Each animal is treated with vehicle or test compounds one hour before the test at appropriate doses and using the oral route of administration.

25 Step 2 - test implementation:

The animal is placed in the lit box, with the head directed towards the tunnel. The number of entries as well as the time spent in the lit box are recorded over a 5 minutes period after the first entry of the animal in the dark box.

The apparatus is cleaned between each animal using alcohol (70°).

30

5. Data analysis and results

All animals scored without entry into the lit box are excluded from the analysis.

A one-way analysis of variance (ANOVA) is used to test whether the mean of the number of entries into lit box or the mean of the time spent in the lit box differs among three or more groups. Where ANOVA indicates a significant difference ($p \leq 0.05$), Fisher's Protected Least Significant Difference is used to compare pairs of group means.

- 5 Results are shown in figures 2a, 2b, 3a and 3b. Compounds A and B are two of the preferred compounds of the invention.

MARBLE BURYING TEST

1. Purpose

- 10 The marble burying test (MB) is used to record the number of marbles buried by mice placed in a novel environment. It has some predictive value for anti-depressant and/or anxiolytic drugs.

2. Background

- 15 Mice, which are placed individually in a cage, bury glass marbles that are present in the cage. This test has been shown to be sensitive to benzodiazepines (BZD's) as these compounds reduce burying behaviour when compared to vehicle-treated control mice, without inducing changes in locomotor activity. Results have shown that in addition to BZD's, this test system is sensitive to the effects of selective serotonin reuptake
20 inhibitors (SSRIs), serotonin noradrenaline reuptake inhibitors (SNRIs) and tricyclic antidepressants (TCAs).

3. Materials

Equipment

- 25 The apparatus consists of transparent polycarbonate cages (30 cm x 18 cm x 19 cm) containing a 5 cm layer of fine sawdust bedding and 20 glass marbles (diameter: 1.5 cm) spaced evenly along the walls of the cage.

Reagents

- 30 • Test substance
• Vehicle

4. Methods

Step 1 - drug treatments:

Animals are randomly assigned to test substance (compound A of the invention) and control groups. Each animal is treated with vehicle or test compounds one hour before the test at appropriate doses and using the oral route of administration.

Step 2 - test implementation:

Each animal is placed individually in the cages where it remains for a 20 min test session. On termination of the test session the animals are removed from the cage and the number of marbles at least two-thirds buried in the sawdust is recorded by an observer unaware of the treatment group.

5. Data analysis and results

A one-way analysis of variance (ANOVA) is used to test whether the mean number of marbles buried differs among three or more groups. Where ANOVA indicates a significant difference ($p \leq 0.05$), Fisher's Protected Least Significant Difference is used to compare pairs of group means.

Results are shown in figure 4.

SPROUTING

Purpose:

Evaluation of antidepressant compounds with regards to their capability to induce neuronal sprouting in hippocampal cell cultures.

Background

Stress can lead to depression and hippocampal damage in animals. In line with these animal findings, patients suffering the PTSD (post traumatic stress disorder) have been shown to have hippocampal damage (and depression). Clinically active antidepressants have been found to induce hippocampal sprouting in cell cultures. Accordingly, a positive effect on sprouting would be a highly wanted aspect of the pharmacological profile of new antidepressants.

1. Primary culture of rat hippocampal neurons

A female rat of 19 days gestation was killed by cervical dislocation (Rats Wistar, Janvier, Le Genest-St-Isle, France), the fetuses were removed from the uterus. Their brains were removed and placed in ice-cold medium of Leibovitz (L15, Gibco, Invitrogen, Cergy-Pontoise). Meninges were carefully removed and hippocamps were dissected out. Hippocampal neurons were dissociated by trypsinization for 30 min at 37°C (trypsin-EDTA, Gibco) in presence of DNase I (Roche, Meylan, France). The reaction was stopped by addition of in medium of Eagle modified by Dulbecco (DMEM, Gibco) with 10 % of fetal bovine serum (FBS, Gibco). The suspension was triturated with a 10-ml pipette and using a needle syringe 21G and centrifuged at 350 x g for 10 min at room temperature. The pellet of dissociated cells was resuspended in L15 medium and was layered over a cushion of 3.5 % solution of bovine serum albumin (BSA) in L15 medium. The tube was centrifuged 10 min at 180 x g. The brake was turned off during the deceleration. The pellet was resuspended in L15 and centrifuged at 350 x g. This final pellet was resuspended in culture medium consisting of Neurobasal (Gibco, ref 21103-049) supplemented with 2% B27 supplement (Gibco, ref. 17504-044), 2 mM L-Glutamine (Gibco).. Viable cells were counted in a Neubauer cytometer using the trypan blue exclusion test (Sigma) and seeded on the basis of 30 000 cells per 35-mm Petri dishes (Nunc) precoated with poly-L-lysine.

Cells were allowed to adhere 2h and maintained in a humidified incubator at 37°C in 5 % CO₂-95 % air atmosphere. Culture medium was then added with tested compounds.

BDNF (Brain –Derived Neurotrophic Factor) (Tebu Peprtech) was tested at 50 ng/ml, a very active concentration, as a reference.

2. Evaluation of the neurite outgrowth

After 3 days of treatment, cultures were washed in phosphate-buffered saline (PBS, Gibco) and fixed in glutaraldehyde 2.5% in PBS.

40 neurons with neurites without branching were taken per condition with a camera (Coolpix 995, Nikon) fixed on microscope (Nikon, objective 20x) and the length measurement were made by analysis of pictures by software (Image-Pro Plus, France).

3. Data analysis

Results are shown in figure 5.

A global analysis of the data was done using a one way analysis of variance (Anova). Where applicable, Fisher's PLSD test was used for multiple pairwise comparison. The level of significance was set at $p \leq 0.05$.
